June 2022

Motivation - U.S.

Record Share of Small Businesses Say They Couldn't Fill Jobs

February survey by National Federation of Independent Business

Couldn't Fill Job Openings

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

Motivation - France

Note: like any business tendency survey variable concerning employment, the results are weighted by the size of the workforce in the enterprises surveyed; for example, in April 2017, the industrial companies reporting recruitment difficulties employed 30% of the workforce in the sector.

◆□▶ ◆□▶ ◆□▶ ◆□▶ □ - つへ⊙

Source: INSEE, business tendency surveys

- 1. How large is the causal impact of hiring difficulties on individual firms' growth?
- 2. How do firms adjust to hiring difficulties?
- 3. Which firms are more sensitive to hiring difficulties?

What we do

- 1. Use granular data on recruiting difficulties (at the vacancy-level)
- Construct shift-share predicted recruiting difficulties (Bartik IV) at the firm-level for French universe, exogenous to the individual firm
- 3. Estimate effects of recruiting difficulties on employment, investment, sales, and profits
- 4. Heterogeneous effects by labor intensity and occupation specificity

What we find

- 1. One std deviation \uparrow in recruiting time (\approx 70 days) is associated with
 - ▶ 5-10% \downarrow in employment
 - Worsening in performance: sales $\downarrow 4\%$, profits $\downarrow 4\%$
- 2. Adjustment margins:
 - Recruiting intensity: reduction in vacancy posting
 - less experience required for new hires
 - Higher retention of incumbents through higher hourly wages

◆□ ▶ ◆□ ▶ ◆三 ▶ ◆□ ▶ ◆□ ◆ ●

- 3. Larger decline in employment for:
 - Labor-intensive firms
 - Firms with high occupation-specificity

Search and Matching Model

- Search and matching model with large firms (Cahuc et al, 2019)
- Value function of the firm satisfies:

$$\Pi(L_{t-1}) = \max_{V_t} A_t \cdot R(L_t) - w_t \cdot L_t - c_v \cdot V_t + \beta E_t \Pi(L_t)$$

subject to the law of motion of employment:

$$L_t = (1-q_t)L_{t-1} + m_t V_t$$

where

- V_t number of vacancies posted
- flow vacancy cost c_v
- expected vacancy time-to-fill $1/m_t$
- job destruction rate q_t

Search and Matching Model

• Denoting time-to-fill $\tau_t = 1/m_t$, after some algebra, we get :

$$d\log L_t = rac{c_v}{w_t}rac{1}{(lpha-1)}d au_t$$

• $\alpha < 1$ is elasticity of labor in revenue function

Time-to-fill depresses labor demand

Heterogeneity Analysis

Data

- Vacancies posted on *pole-emploi.fr*: occupation, location, posting firm id (and its industry), publication date, recruitment success, and delisting date
- Matched employer-employee registers (DADS): employment spells with occupation
- Firms' balance-sheet panel data: investment, profits, sales
- Sample: universe of French firms in private sector existing in 2009, observed until 2017 (excluding financial sector)

◆□ ▶ ◆□ ▶ ◆三 ▶ ◆□ ▶ ◆□ ◆ ●

➡ Summary statitics

Pole-emploi vacancy data

- Operated by *Pole emploi*, the French Public Employment Service
- Any private firms can post online and screen job seekers profile (free of charge)
- Large coverage: almost 50% of hires with online advertising use pole-emploi.fr (OFER firm survey in 2016)
- Pole-emploi employees manage the website and monitor posting firms (record recruitment success, clean out inactive vacancies if needed).

Heterogeneity Analysis

Identification

 \blacktriangleright Consider following naive OLS regression firm \times year level

 $Emp_{it} = \delta RecTime_{it} + FirmFE_i + yearFE + \epsilon_{it}$

• δ biased for instance by:

market-level productivity or demand shock

- ▶ direct ↑ in employment
- ▶ \uparrow labor market tightness $\rightarrow \uparrow$ firm-level recruiting time
- firm-level productivity or demand shock
 - ▶ direct ↑ in employment
 - \blacktriangleright \uparrow firm-level recruitment effort $\rightarrow\downarrow$ recruiting time

To achieve identification, we exploit exogenous variation in recruiting difficulty at firm-level based on shift-share analysis

Empirical design

- Exogenous firm-level variation in recruiting difficulty based on shift-share analysis:
 - Shifts: RecTime_{kzt,-j} average recruiting time in year t, commuting zone z, occupation k, leaving out own industry j
 - 2. **Shares**: *s*_{*ik*,2009} employment share of occupation *k* within firm *i* in 2009
- For each firm i in year t, the shift-share instrument for recruiting time is given by:

$$\widehat{RecTime}_{it} = \sum_{k} s_{ik,2009} \times \overline{RecTime}_{kzt,-j}$$

◆□ ▶ ◆□ ▶ ◆三 ▶ ◆□ ▶ ◆□ ◆ ●

Empirical design

Panel at firm × year level

 $Perf_{it} = \delta RecTime_{it} + FirmFE_i + ComZone \times Industry \times yearFE + \epsilon_{it}$

where *Perf_{it}* is either employment, investment, sales or profits firm *i* in year *t*

RecTime shift-share prediction of recruiting time

Standard errors are clustered at the commuting zone level

Labor Intensive vs Not Labor Intensive

Labor intensive: emp in 2009/total asset above median

◆□ ▶ ◆□ ▶ ◆三 ▶ ◆□ ▶ ◆□ ◆ ●

Low vs High occupation specificity

- Sample of all firm-to-firm transitions
- Compute the number of transitions from occupation O to occupation D
- Occupation specificity: for every occupation D, compute the share of transitions coming from the same occupation

for every firm, compute the average of the occupation specificity of its employees in 2009

Low vs High occupation specificity

Specificity of average firm-level occupation in 2009 (above median)

Conclusion

- Hiring difficulty hamper firms growth and profitability
- Firms adjust through various margins, changing vacancy requirements, retaining more incumbents, increasing hourly wages
- Effects are stronger for labor-intensive firms, and firms with specialised workforce.

Motivation Europe

Enterprises with hard-to-fill vacancies for ICT specialists, 2018

(% of enterprises that recruited or tried to recruit, without financial sector)

ec.europa.eu/eurostat

Motivation US JOLTS

The ratio of job openings to hires has never been higher

A ratio of 1 means open jobs are filled within a month on average. A higher ratio means it takes longer.

Empirical design: assumption discussions

- Key comparison: firms X and Y in same industry and commuting zone with firm X employing more occupation A workers at baseline; shocks on recruiting time for occupation A in other industries; how does employment of firm X change wrt firm Y?
- Identification robust to endogeneity of shifts: baseline shares are exogeneous, i.e. not correlated to firm-specific productivity shock simultaneous to occupation-specific shocks (Goldsmith-Pinkham et al 2020)
- Identification robust to endogeneity of shares: shocks are exogenous
